

REGIONALES RECHENZENTRUM ERLANGEN [RRZE]

Modules and Software Installation

HPC Services, RRZE

Which packages are available

- RRZE HPC team uses **standard distribution packages**
 - On **frontend** nodes: **Full** installation and easy to add packages
 - On **compute** nodes: **Stripped** installation due to diskless setup
 - › The OS and software is occupying memory
 - › More software → Less memory for your applications
 - HPC software is centrally installed and accessible through **modules**
 - › Compilers, libraries, commercial and open software
- If **multiple** users **reasonably** request packages, we can add them

The module system

The modules system

- The `modules` system is a **de-facto standard** on HPC systems
- **BUT:** Every facility uses the modules differently
 - RRZE: `<name_of_software>/<version>(-<requirements>)`
 - Examples: `intel64/19.0up05` and `openmpi/2.0.2-gcc`
 - Some centers use categories like MATH, LIBRARIES, etc.
(`module load MATH; module load module_in_math`)
- The `modules` system affects **only current and sub-shell!**

The modules system

RRZE: Modules in categories ,deprecated' and ,testing' might be deleted without notice

Show available modules: **module avail**

```
$ module avail
----- /apps/modules/data/applications -----
cp2k/2.5.1          gromacs/2019.3-mkl-IVB(default)  openfoam/4.1-trusty
gnuplot/5.0.1      gromacs/2019.5-mkl-IVB          openfoam/5.0-trusty
gromacs/2016.4-mkl gromacs/2019.5-mkl-IVB-CUDA101  paraview/4.2.0-x86_64
[...]
```

Show all modules of software: **module avail gcc**

```
$ module avail gcc
----- /apps/modules/data/applications -----
----- /apps/modules/data/development -----
gcc/4.9.3 gcc/5.4.0 gcc/6.1.0 gcc/7.3.0 gcc/8.1.0
```

The modules system

Some module load / unload other modules automatically

Load a module: **module load <modulename>**

```
$ module load intel64
```

```
$ module list
```

```
Currently Loaded Modulefiles:
```

```
1) intelmpi/2017up04-intel 2) mkl/2017up05
```

```
3) intel64/17.0up05
```

Unload a module: **module unload <modulename>**

```
$ module unload intel64
```

```
$ module list
```

```
No Modulefiles Currently Loaded.
```

The modules system

Command	What it does
<code>module avail</code>	List available modules
<code>module whatis</code>	Shows over-verbose listing of all modules
<code>module list</code>	Shows which modules are currently loaded
<code>module load <pkg></code>	Loads module <i>pkg</i> , i.e., adjusts environment
<code>module load <pkg>/<version></code>	Loads specific version of <i>pkg</i> instead of default
<code>module unload <pkg></code>	Undoes what the load command did
<code>module help <pkg></code>	Shows a detailed description of <i>pkg</i>
<code>module show <pkg></code>	Shows what environment variables <i>pkg</i> modifies and how

The modules system and the batch system

- Shebang in batch scripts: `#!/bin/bash -l`
- **Some packages** compile library paths into the application
→ Don't rely on it! **Always load** required modules
- On **meggie** in batch scripts:
 - `#SBATCH --export=NONE` **and** load required modules
 - `unset SLURM_EXPORT env`

Software Installation

Software installation

The handy but later annoying approach

- Many packages use **configure & make**:
 - Setup: `./configure --prefix=$HOME/Apps` (other opts)
 - Compilation: `make`
 - Installation: `make install`
- Or **cmake & make**:
 - Setup: `mkdir BUILD && cd BUILD`
`CMAKE_INSTALL_PREFIX=$HOME/Apps cmake ..`
 - Compilation: `make`
 - Installation: `make install`

Software installation

The handy but later annoying approach

- At compilation add `$HOME/Apps/include` and `$HOME/Apps/lib`
- Add library path at runtime (only current shell):

```
export LD_LIBRARY_PATH=$HOME/Apps/lib:$LD_LIBRARY_PATH
```
- **But** how to uninstall?
Commonly there is **no** `make uninstall`
- **But** how to upgrade?
Files from old install might not be overwritten

Software installation

Further pitfalls

- Check build before running in production!
- Some packages require special build preparations:
 - GROMACS: `build_type=Release` or binary crashes often
 - Adjust paths to dependencies in config files
 - Activate required feature only with non-default build flag
- What to do with compiler errors?

Software installation

Recommendations

- If you install own software, use **distinct folder** for each version:
 - Separate installations: `$HOME/Apps/libX- (<cluster>-)Y.Z`
 - Simple to delete old versions (`rm -r $HOME/Apps/libX-Y.Y`)
 - In case of space problems: Use `$WORK` (**No backups!**)
- Helpful but not a silver bullet: **package managers**
 - [easy build](#)
 - [spack](#)

Package manager Spack

- Developed at LLNL
- Resolves complicated dependencies among the packages
- **Issue:** Spack always rebuilds complete tree, hard to integrate common OS packages
 - Check `/apps/SPACK/spack/etc/spack/packages.yaml` for cluster-specific settings (like always use installed SLURM version)
 - **Problem:** Space in `$HOME` directory limited, may use `$WORK`
 - **Issue:** Currently no way to use Intel-MPI 19.X due to bug

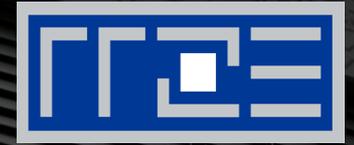

Software installation

Language specific package managers

- **Python:** pip, virtualenv, conda
System Python contains only few modules, **try Anaconda Python!**
- **R:** CRAN
- **Perl:** CPAN

- Use `--user` flag (or similar) to install in `$HOME`
(for `$WORK` use `export PYTHONUSERBASE=$WORK`)

REGIONALES RECHENZENTRUM ERLANGEN [RRZE]

Thank you very much

HPC@RRZE

Adding module for own installations

- Assuming you have use distinct folders (`~/Apps/libX-x.y.z`)
 - Create hidden folder: `mkdir -p ~/.modfiles/libX/`
 - For each version create a file: `edit ~/.modfiles/libX/x.y.z`

```
#%Module1.0
## libX
##
module-whatis "libX: The library for doing stuff with X"
conflict libX

set                pkghome                ~/Apps/libX-x.y.z
prepend-path PATH  $pkghome/bin
prepend-path LD_LIBRARY_PATH $pkghome/lib
setenv LIBX_LIBDIR "$pkghome/lib"
setenv LIBX_INCDIR "$pkghome/lib"
```

- Finally: `module use ~/.modfiles` (e.g. in `~/.bashrc`)
